

2-98 Anemone 1A

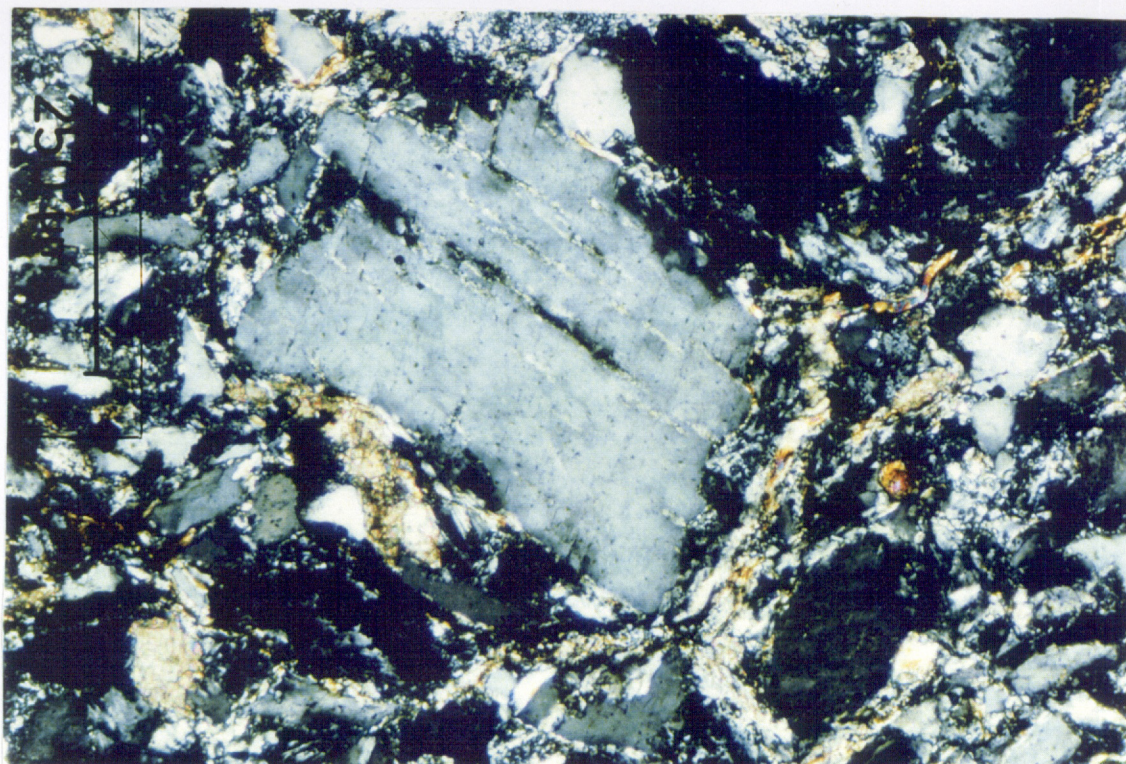

Figure 12 - Anemone #1A, junk sub sample, 4676a m. Under crossed polars, the same view shows sericite in feldspar cleavage and illitic matrix. Brownish stringers in the previous photo are shown to consist of illite. Highly birefringent spar occurs in the matrix. A bright pink-yellow detrital mineral (apatite?) is evident in the lower right of the photo.
