1. INTRODUCTION

A. Well and Rig Data

Operator:

ESSO Australia Ltd.

Well Name:

Terakihi No.1

Location:

Offshore Gippsland Basin,

Bass Strait Victoria

Position:

Lat: 38° 30′ 20.70″ South Long: 148° 32′ 43.23″ East

Field:

Exploration

Permit:

VIC/P24

Rig:

Southseas "Southern Cross"

Semi-submersible

RKB - MSL:

21 metres

RKB - SB:

424 metres

Spud Date:

30th March 1990

Total Depth:

3040 meters

Completion Date:

21 st April 1990

Completion Status:

Cased and suspended

Exlog Unit:

244, GEMDAS X

Crew - Gemdas:

M. Sale, D. Thornton, D. New,

D. Marburger

Logging:

H. Naim, A. Thangam, M. Orr,

D. Marburger

Tritium:

D. Rozendaal, G. Norton.

B. Prognosis

Terakihi-1 was a wildcat exploration well drilled 20.0 km to the west-north-west of the Mackerel platform in the Bass Strait by the semi-submersible drilling rig "Southern Cross". The well was programed to reach a total depth of 2971m (RKB) and to take 39 days from spud to the rig release date. The closest wells are Hapaku-1 (5.0 km to the south-south-east), Blackback-1 (5.0 km to south-east), Volador-1 (9.0 km to the north) and Mackerel-1, 9.0 km to the north.

Terakihi-1 was proposed to evaluate the hydrocarbon content of an erosional remnant mapped at the top of the Latrobe Group and sealed by the Lakes Entrance Formation. Thus, the primary targets were the top Latrobe sands.

Exploration Logging provided a Geological Engineering Monitoring and Data Acquisition System (GEMDAS) service from spud, with Formation Logging and Pressure Evaluation services on Terakihi No.1 from the start of the 12.25" hole at 1141m to total depth. Continuous evaluation of pressures and drilling progress from real time data will provide an aid in optimising drilling costs and ensure drilling continues with maximum safety to personnel, the well and equipment.

The operator was continuously advised as to the status of these analyses. The printouts and plots of the results and services are contained in the appendices of this report.

2. DRILLING AND ENGINEERING

a. Well History

Terakihi No.1 was spudded on the 30th March 1990 at 06:30 hours by the semi-submersible drilling rig "Southern Cross". All depths unless otherwise stated are in metres along hole below the RKB. RKB to mean sealevel was 21m and RKB to seafloor was 424 metres (sea depth 403 metres).

26" Hole Section: 424 to 551 metres.

After ballasting the rig to drilling depth, the TGB was run to the seafloor, due to a considerable angle, it was pulled and a section of 13.375" casing welded to it to aid in stability.

NB#1, a HTC R1 26" run with a 26" hole opener, spudded Terakihi No.1. This bit drilled to 551m, a distance of 127m in 3.3 hrs at an average rate of penetration of 38.5 m/hr. The drilling fluid was seawater with Hi Vis sweeps being circulated on each connection. At 551m the hole was swept with a 100 bbl Hi Vis pill, a survey dropped and the bit tripped to the seafloor. The bit was tripped back to bottom with no fill and a 250 bbl Hi Vis pill was spotted, three stands pulled and another 250 bbl Hi Vis pill spotted, and the bit pulled to run casing.

Casing (10 joints of 20", X52, 94 ppf) was run with the shoe set at 540m. The casing was cemented with 750 sx class "G" cement at 13.2 ppg followed by 600 sx class "G" cement with 1.15% CaCl at 15.8 ppg.

17.5" Hole Section: 551 - 1141 meters

After running the marine riser and BOP stack, the 17.5" BHA and NB#2, a HTC X3A, was run in the hole to the top of cement at 533m. The cement and shoe were drilled to 551m and new hole drilled to 1141m with no problems. At 1141m, bottoms-up was circulated, and a survey dropped (dev = 0.25° at 1141m). A 100 bbl Hi Vis slug was pumped around the hole to sweep the riser, and a slug pumped prior to pulling out of the hole to the shoe, where the survey barrel was retrieved. The bit was then run back to bottom with no fill being recorded. Bottoms-up was then circulated to condition the mud and a slug pumped prior to pulling out of the hole to run wireline logs. Wireline logs were then run (BHC-GR-Cal) without problems. The bit made 590m in 11.1 hrs (on-bottom) with an average rate of penetration of 53.2 m/hr, and was graded T2 B2 G0.

Casing (60 joints of K55, 54.5 lb/ft, 13.375") was then run with the shoe set at 1124m. The casing was cemented with 1000 sacks of class "G" cement at 15.8 ppg.

After testing the BOP's, NB#3, a Hycalog PDC DS40, was run in and drilled cement and the shoe track from 1100m. New hole was drilled to 1144m where bottoms-up was circulated and a leak-off test performed. With a gauge pressure of 1300 psi, this gave a fracture pressure of 16.0 ppg EMW.

Drilling continued with NB#3 from 1144m to 1214m where returns were circulated, a survey dropped (dev = 0.5°) and the bit tripped due to low rate of penetration. No overpull was recorded during the trip out. NB#3 drilled from 1141m to 1214m, a distance of 73m, in 5.7 hrs at an average rate of penetration of 12.4 m/hr and was graded 10% worn. The lithology was limestone grading to calcareous claystone.

NB#4, a HTC ATJ1 12.25" was run in the hole with no problems and no fill. Drilling continued at rates of penetration varying from 10 to 30 m/hr to 1774m where the bit was tripped due to high bit hours and a low rate of penetration, having drilled 560m in 33.9 hrs at an average rate of penetration of 16.5 m/hr. The bit was graded as T3 B3 G0. The lithology was limestone, occasionally grading to calcareous claystone. Tight hole was recorded on the trip out, with up to 80 klb overpull being recorded from most stands to the shoe.

RRB#3, a Hycalog PDC DS40 12.25" bit was run in with no problems. Drilling continued through the Gippsland Limestone to 2273m at rates of penetration ranging from 10 to 40 m/hr. At 2273m a Hi Vis pill was circulated, a survey dropped (misrun) and a 20 stand wiper trip made with no hole problems. Drilling then continued through the Gippsland Limestone at rates of penetration varying from 10 to 25 m/hr to 2475m where the rate of penetration increased to over 30 m/hr marking the top of the Lakes Entrance formation. At 2506m the Seawater-gel mud system was displaced with a KCl-Polymer mud system. Drilling continued through the calcareous claystones of the Lakes Entrance Formation at rates of penetration varying from 20 to 50 m/hr. At 2841m the rate of penetration increased to over 60 m/hr and a flow check was made at 2844m with no flow. This drilling break marked the top of the Latrobe Group, the primary target, and bottoms-up was circulated with a maximum gas of 16% (800 u) and C1-C5 being recorded. Based on this it was decided to core, and a wiper trip was made to the shoe with overpull of up to 100 klb being recorded from the interval 2776m - 2498m on the trip out. The bit was run back to bottom with no problems and bottoms-up circulated with a trip gas of 64u (1.28%) recorded. The bit was then pulled with no hole problems. RRB#3 drilled from 1774m-2844m, a distance of 1070m in 41.2 hrs (on-bottom), at rates of penetration varying from 10 to 60 m/hr and averaging 26 m/hr.

CB#1, a Christenson RC476 12.25" (rerun from a previous well and graded at 20% worn), and the core barrel were picked up and run in the hole with the interval 2830m - 2844m being reamed on the way in. Bottoms-up was circulated, the ball dropped, and Core-1 was cut from 2844m to 2862.5m (18.5m) in 1.4 hrs at an average rate of penetration of 13.2 m/hr. Tight hole was noted from the first two stands of the trip out with a maximum

overpull of 100 klb. It was not possible to pump a slug resulting in a wet trip. While breaking out the core barrel, it was discovered that the top joint of the inner fiberglass sleeve had become jammed in the outer barrel and had broken off at both the top and bottom. Both sleeves were layed down and 12.6m (68%) of sandstone recovered. As there were indications of hydrocarbons in the bottom of the core it was decided to continue coring.

The core barrel and RRCB#1 were run in the hole to 2805m and the interval 2805m - 2862.5m reamed with tight hole being noted at 2839m. Bottoms-up was circulated with a trip gas of 110 units (2.2%) and the ball dropped. When the ball seated the pump pressure surged to 2000+ psi before returning to normal. It is likely that the fiberglass sleeve was jammed against the outer barrel and that this pressure surge burst the sleeve. Core-2 was then cut from 2862.5m to 2881m, a distance of 18.5m, in 1.7 hrs at an average rate of penetration of 10.9 m/hr. Tight hole was again noted on the trip out and it was necessary to pick up the kelly and backream from 2881m - 2788m. This tight hole may have been due to cuttings packing off round the BHA as the annular velocities while coring were low. The core sleeves were layed down (the top sleeve was broken about 5m from the top) and 9.9m (53.5%) of sandstone recovered.

The BOP's were tested and NB#6, a Smith F27D, picked up and run in the hole to 2800m where the kelly was picked up and the interval 2800m -2881m reamed/washed to bottom. Drilling continued through the sandstones of the Latrobe Group at rates of penetration varying from 60 to 2 m/hr. The torque seen on this bit run was erratic and often very high and the bit had to be pulled up and worked back to bottom on many occasions. At 3040m TD was reached, bottoms-up circulated, and a 10 stand wiper trip made with only minor overpull being noted on the trip out. Bottoms-up was again circulated, a survey dropped (misrun) and the bit pulled to run logs. NB#5 drilled 159m in 15.4 hrs (on bottom) at an average rate of penetration of 10.3 m/hr.

Wireline logs were then run as follows:

Run 1: DLL-MSFL-LDT-CNL-GR-Cal

Run 2: RFT (10 pressure points, 1 sample)

Run 3: RFT (Two samples)

Run 4: BHC-GR-Cal

Run 5: SHDT

Run 6: WST

Run 7: CST (Shot 30, recovered 27)

On the basis of core and log data it was decided to case and suspend the well and RRB#6 was picked up and run in the hole for a wiper trip. The interval 2995m-3040m was reamed/washed on the trip in and a 100 bbl Hi Vis pill circulated with common small, blocky to platy, cavings (possibly from the Latrobe Group) being noted on bottoms-up. The kelly was rat-holed and an attempt made to pull out of the hole. This was not possible due to the BHA packing off and the kelly picked up and a 200 bbl Hi Vis pill circulated. Common fresh platy cavings (also from the Latrobe Group) were noted on bottoms-up. The hole instability did not appear to be due to overpressuring as the

cavings were fairly small and were not curved. It is possible that the Latrobe Group siltstones are microfractured as this would produce the type of cavings seen. A wiper trip was then made to 2450m with the kelly being used to pump out singles over the interval 3010m - 2995m on the trip out and the same interval being reamed on the trip in. A 90 bbl 15.3 ppg pill was circulated and the bit pulled with the interval 3010m - 2995m being worked on the trip out.

Casing (222 joints of 9.625", N80, 47 lb/ft) was then run and cemented with the shoe at 3001m. The wellhead was then secured and the rig released.

B. Bit Optimisation

Bit performance was continuously monitored and the operator advised of cost performance, rate of penetration, torque and formation changes. Cost analysis was performed on the basis of bit cost, rig cost and an average tripping speed and are a guide only. A plot of the results and a bit record can be found in the attached appendices. No bits were pulled purely on a cost basis.

The 26" hole section was drilled with a Reed R1 (IADC 111), rerun from the previous well, a distance of 127m, in 3.3 hrs, at an average rate of penetration of 38.5 m/hr and was graded at T1 B1 G0 and could be rerun. The bit was pulled to run 20" casing.

The 17.5" hole section (a distance of 590m) was drilled with NB#2, a HTC X3A. The bit run was 11.1 hrs through argillaceous limestones of the Gippsland Limestone at an average rate of penetration was 53.2~m/hr. The bit was pulled to run 13.375" casing and was graded T2 B2 G0.

The 12.25" section was drilled with 1 tooth, 1 PDC bit (run twice), 1 rerun core bit (also run twice) and 1 insert tricone bit. This 1899m section was drilled in 99.3 hrs at an average rate of penetration of 19.1 m/hr.

NB#3 was a PDC DS40 12.25" bit which drilled the shoe and 73m of new formation in 5.7 hrs at an average rate of penetration of 12.8 m/hr. The bit was in good condition when pulled and the low rate of penetration may have been due to the formation (limestone) being too soft for this type of bit and it is suggested that this type of bit would be more suited to the slightly firmer mid-Gippsland Limestone.

NB#4, a HTC AT-J1 was then run and drilled from 1214m to 1774m, a distance of 560m, in 33.9 hrs at an average rate of penetration of 16.5 m/hr. The bit was pulled at 1774m due to a decrease in rate of penetration and high bit hours. This bit

suited the unabrasive limestone through which it drilled and was graded as T2 B4 G0.

RRB#3, a Hycalog DS-40 12.25" PDC bit was run next and drilled from 1774m to 2844m, a distance of 1070m in 41.2 hrs (onbottom) at an average rate of penetration of 26.0 m/hr. While this bit was suited to the argillaceous limestones of the Gippsland Limestone and averaged over 23 m/hr it was ideal for the calcareous claystones of the Lakes Entrance Formation and drilled at an average of 34 m/hr through this formation. The bit was tripped at 2844m to cut core 1 and was 40% worn. Cuttings seen during this bit run were generally of good quality although smaller than those produced by a conventional bit. The rates of penetration seen during this bit run were not as dependant on lithology as those from a conventional bit would have been. However there was still enough variation in the rate of penetration for this to be used to determine changing lithology while drilling, for example at the top of the Latrobe the rate of penetration increased from 30-40 m/hr in the claystones to over 60 m/hr in the sandstone.

A Christenson RC476 core bit was run next and cut Cores #1 and #2 from 2844m to 2881.0m (37.0m) in 3.1 hrs at an average rate of penetration of 11.9 m/hr with only. The bit, which was rerun from a previous well was graded as 20% worn prior to the start of coring and 45% at the end. Most of the bit wear appears to have been caused by cemented sands seen in the second core.

NB#6 was a Smith F27D and drilled through siltstones and abrasive sandstones of the Latrobe group and was pulled at 3040m (TD) to run logs. This bit drilled 159m in 15.4 hrs (on bottom) at an average rate of penetration of 10.3 m/hr. High and very erratic torque, frequently causing the rotary table to stall out was seen while drilling with this bit. Wireline logs indicated that this section of hole was exactly in-gauge and the torque may have been caused by the stabilizer hanging up in tight hole.

C. Hydraulics Optimisation.

Hydraulic analyses were provided for ESSO Australia on a daily basis and as required. Results of these analyses are provided on the daily Gemdas report and on selected hydraulic printouts in Appendix D.

The Southern Cross was equipped with two Oilwell A-1700PT triplex pumps (12" stroke) fitted with 6.5" liners to give a 5.00 gal/stk output at 97% efficiency for Terakihi No.1.

The 26" hole section was drilled with seawater and high-viscosity sweeps. This along with moderately high annular velocities, ensured adequate hole cleaning through this interval. The hole was displaced with high viscosity mud prior to running casing and the riser.

The 17.5" section was drilled with seawater and high-viscosity sweeps on every second connection with flow rates of around 950 gpm. These flow rates were sufficient, with the Hi Vis sweeps, to keep the hole clean but low enough to prevent any serious hole washout. As native low gravity drilling solids began to increase the mud density, the sand traps were dumped every connection and water was added constantly to maintain mud weights at around 9.3 ppg. Bit hydraulics through this section were generally good, with a jet impact force of 7.6 lb/sq" and a hydraulic power of 800 hp.

The 12.25" section to 2500m was drilled with seawater-gel mud system with native clays from the formation being used to maintain viscosity. At 2500m the mud system was converted, while drilling, to a KCl-Polymer mud and this system was used to TD. Mud weights increased from 9.2 ppg at 1144m to 9.5 by 1774m and then remaining at around 9.5 -9.6 ppg. to TD .

Moderately high flow rates (750 to 800 gpm) were used in this hole section (apart from while coring) giving annular velocities of 50 ft/min in the riser and 220 - 230 ft/min at the drill collars. These appeared to be sufficient to keep the hole clean as no fill was noted after trips. While coring flow rates were only 220 gpm, resulting in low annular velocities (only 14 ft/min in the riser) and hence inefficient cutting removal. This probably contributed to the cutting packing off round the BHA and the tight hole seen after each core. Critical velocities at the collars were estimated to be 300 ft/min with the seawater-gel mud and 400 ft/min (Power law model) with the KCl-Polymer mud. Thus the flow regime was probably laminar throughout the system and hence hole washouts were kept to a minimum. This was verified by carbide data which indicated that the hole above 2500m was either in-gauge or slightly undergauge but that below 2500m some washouts were occurring, mainly in the sands of the Latrobe Group.

Nozzles sizes and flow rates were chosen to give as near optimal bit hydraulics as possible while keeping the pump pressures below 3000 psi. On the first run with the PDC bit 3x13 and 2x15 nozzles were used resulting in a hp at the bit of only 3.7 hp/sq in. This comparatively low hp may have contributed in part to the low rate of penetration seen on this bit run. For the remainder of the 12.25" hole (apart from the cored interval) bit hydraulics were near optimal resulting in good penetration rates.

D. Borehole Condition

The borehole condition was monitored during drilling and tripping by observing the overpull or drag associated with tripping and connections which would indicate tight hole or other problems. Torque measurement was also utilised as an aid in bore hole analysis. Carbides were run periodically and the average open hole size for an interval calculated on the return

of the maximum gas peak. Wireline caliper logs were looked at to pin point major hole washouts occurred and to correlate these if possible with lithology.

No hole problems were seen while drilling either the 26" or 17.5" hole sections. Maximum deviation was 0.5° in the 26" hole and 0.25° in the 17.5" hole.

Hole problems in the 12.25" hole section above 2800m were generally restricted to tight hole, with up to 100 klb overpull, on the first trip through a newly drilled section. This was generally attributed to the slight hydrating and swelling of the clays in the Gippsland Limestone and Lakes Entrance Formations. On both trips out of the hole with the core barrel the BHA was initially packed off and up to 100 klb overpull was recorded. This was probably due to the low flow rates and annular velocities used while coring being insufficient to remove the cuttings and lost core from the hole.

Hole problems were also noted on the wiper trip after logging with the interval 2995m to 3040m was reamed/washed on the trip in. A 100 bbl Hi Vis pill was circulated at 3040m with common small blocky to platy cavings (from the Latrobe Group?) being noted on bottoms-up. The kelly was rat-holed and an attempt made to pull out of the hole. This was not possible due to the BHA packing off and the kelly picked up and a 200 bbl Hi Vis pill circulated. Common fresh platy cavings (also from the Latrobe Group) were noted on bottoms-up. The hole instability did not appear to be due to overpressuring as the cavings were fairly small and were not curved. It is possible that the Latrobe Group siltstones are microfractured as this would produce the type of cavings seen. A wiper trip was then made to 2450m with the kelly being used to pump out singles over the interval 3010m -2995m on the trip out and the same interval being reamed on the trip in. A 90 bbl 15.3 ppg pill was circulated and the bit pulled with the interval 3010m - 2995m being worked on the trip out.

Torque was often high and erratic while the PDC bit was being run. This was thought to be due to either the action of the cutting surfaces on the formation or the stabilizer hanging up in in gauge or rugose hole. From 2881m to 3040m very high, erratic, torque was recorded, frequently causing the rotary table to stall out necessatating the bit being pulled up and worked back to bottom. This tight hole may have been due to the stabilizer hanging up in in gauge hole however the nature of the cutting seen while circulating Hi Vis pills after logging indicates that the silstones of the Latrobe may be microfractured. If this were the case then the high torque may have been produced by the action of the bit on the fractures rather than the stabilizer.

Carbides run at 1525m, 1755m and 2206m indicated that the hole was undergauge with a minimum diameter of 10.8" at 1755m. Carbides and other lag data indicated that below 2200m the hole was washedout to a maximum of 13.0" at 2598m.

Hole deviation varied from 0.5° at 1214m to 2.75° at 1774m and 2844m to give a true vertical depth of 3038.26m at TD (3040m). No doglegs were present and no problems from keyseats etc were noted.

3. PRESSURE EVALUATION

A. Formation Fracture Pressure

Formation fracture pressures were calculated during drilling and recorded in the daily reports (Appendix C). Plotted data can be found in Appendix B (iii). Offset well data from Blackback No.1 was used in the calculation of an initial overburden gradient for the well. Once density data became available from logs the overburden gradient was recalculated and this data used to determine the final fracture gradient.

One formation integrity test was performed as follows:-

Hole Depth	Hole Size	Casing Shoe (m)	Mud Dens (ppg)	Fracture Press; EQMD(ppg) PSI;
1144	12 "	1124	9.2	16.0 3062

Data from this test and the estimated overburden gradient was used to determine fracture pressures while drilling and the results of these calculations reported to the operator each morning or as required.

No significant downhole mud losses were recorded while drilling Terakihi No.1. The minimum estimated fracture pressure in the 12.25" hole section was 16.0 ppg EMW at the 13.375" casing shoe this was significantly higher than the maximum equivalent circulating density of 9.8 ppg and mud losses due to hydraulic fracturing were therefore considered unlikely.

B. Formation Pore Pressure

Formation pore pressure indicators were monitored on a continuous basis while drilling and pore pressure estimates were reported to the operator daily, or whenever significant variations were encountered. Plots of the relevant pore pressure indicators are available in Appendix B (iii).

The 26" hole was drilled with returns to the seafloor and therefore no meaningful pressure analysis is possible for this section (424m - 551m).

Connection gas were encountered from 551m - 700m whilst drilling with 8.7 ppg mud indicating that the pore pressure may have increased slightly to 8.6 - 8.7 ppg EQMD, which is within the region expected from a salt water pressure gradient. The origin of this gas is thought to be from a biogenic window within the Gippsland Limestone. By 700m mud weight increased to 9.3 ppg and no connection gas was encountered. Other indicators suggest that the pore pressure gradient remained normal in the 17.5" hole.

Pore pressure through the 12.25" hole section appears to have remained normal at 8.5 ppg EMW. The most reliable pressure indicators through this section were gas values, which was

generally low, and cavings which were generally only minor. While trip gasses of up to 64u were recorded the peaks were fairly sharp and gas values quickly returned to normal after bottoms up. The tight hole seen on trips and while drilling below 2844m was attributed cuttings packing off round the BHA and to the stabilizer hanging up in gauge hole and was not an indicator of increasing pore pressure.

The Dxc plot was of little value below 1774m due to the use of a PDC bit this depth to the top Latrobe. Below 2881m a conventional insert bit was used and Dxc indicated a normal trend.

Flowline temperature was damped and unresponsive due to heat loss in the riser and pits and was of little value in pressure detection. A gradual warming trend was noted to 2880m where both temperature in and temperature out showed a trend reversal and from 2880m to 3040m temperatures decreased. However delta T remained constant and this trend reversal was attributed to a decreasing ambient temperature at this time.

RFT's were run through the Latrobe sands and indicated that the formation was normally pressured at 8.35 ppg EMW and indicated a maximum formation pressure of 4048 psi at 2868.5m to give an extrapolated bottom hole pressure of 4292.4 psi. The RFT data indicates a near freshwater gradient for this well and hence a lower than estimated normal formation pressure gradient.

4. GEOLOGY AND SHOWS

Lagged cuttings samples were collected at 10m intervals from 1144-2600m, and then at 5m intervals to TD. Spot samples were also taken on all gas peaks or on bottoms up from significant drilling breaks to aid in lithological identification. All regular samples were packaged by EXLOG personal and distributed as per Esso's requirements.

A FID total gas detector, FID chromatograph, CO2 detector and H2S sensor were used to analyze all formation gasses and the results shown on the mudlog. A fluoroscope was used to check for liquid hydrocarbons. Gas values down to the top Latrobe at 2840m were generally low and no shows were seen. At 2840m a drilling break was noted and bottoms-up were circulated at 2844m with 800u (16%) gas being recorded from bottoms up. No fluorescence was seen in the mud or cuttings but the presence of C1-C5 in the gas indicated the possible presence of oil and two cores were cut. Good shows were seen in the top of the first core with up to 90% bright yellow white fluorescence with good cut being recorded (see appendix D: Core Descriptions). Gas values below the cored interval were low indicating that this interval was water saturated. Log analysis indicated 15m of gross pay over the interval 2840m - 2855m.

All depths below RKB :

551 to 1144 metres NO SAMPLES REQUIRED

1144m to 1240metres

LIMESTONE: light to medium grey, calcarenite to calcailtite, soft to firm occasionally moderately hard, trace forams with common fossil fragments. Minor trace pyrite, trace foraminifera.

1240 to 1450 metres

LIMESTONE: medium to light grey, occasionally off white to medium brown, calculative to occasionally calcarenitic, slightly to occasionally very argillaceous, common micro and macro fossil fragments, common foraminifera, rare carbonaceous flecks, soft to occasionally firm, subblocky.

1450 to 1850 metres

LIMESTONE: medium to light grey and light grey brown to occasionally medium brown, calcilutitic-calcisiltitic, trace to occasionally common calcarenite, moderately argillaceous in part, trace foraminifera and fossil fragments, rare carbonaceous flecks, soft to occasionally firm, sticky, subblocky.

1850 to 2200 metres

LIMESTONE: light olive grey to medium grey brown, calcilutitic to calcisiltitic, moderate to common calcarenite, argillaceous in part, trace foraminifera and glauconite, trace pyrite and

carbonaceous flecks, soft to occasionally moderately hard, blocky to subblocky.

2200 to 2480 metres

LIMESTONE: light to medium grey, occasionally dark grey brown, calcisiltitic, common calcarenite, moderately to very argillaceous in part, trace glauconite and foraminifera, rare pyrite and carbonaceous flecks, firm to moderately hard, blocky to occasionally subfissile.

2480 - 2510 metres

Shakers being bypassed, no samples.

2510 - 2650 metres

CALCAREOUS CLAYSTONE: very light grey to medium grey to light olive grey, very calcareous, trace foraminifera and glauconite, rare carbonaceous flecks, rare medium to coarse subrounded quartz grains, soft to firm, sticky in part.

2650 - 2840 metres

CALCAREOUS CLAYSTONE: medium grey to medium dark grey, soft to firm, occasionally moderately hard, very calcareous, silty in part, trace carbonaceous/coaly detritus, trace diseminated pyrite and foraminifera, occasional fine clear quartz grains, blocky to subfissile.

Top Latrobe Formation at 2840m (RKB)

2840 - 2856 metres

Core 1: 2844m - 2862.5m

SANDSTONE: off white to light grey, clear to medium grey grains, loose to friable, medium to conglomeratic, dominantly coarse to very coarse, poorly sorted, subangular to rounded, no cement or matrix, trace lithic grains, very good visual porosity.

SHOWS: The sandstone has 70% to 90% bright yellow white fluorescence giving a fast streaming moderately bright cut fluorescence with a thick to thin ring residual. The core sample had a strong hydrocarbon odor.

Note: Fluorescence only seen in the core samples. No fluorescence was seen in the cuttings samples.

2856 - 2881 metres

SANDSTONE: off white to medium grey, occasionally medium brown grey, clear to dark grey grains, loose to occasionally hard, fine to conglomeratic, dominantly fine and very coarse (bimodal), poorly sorted, subangular to dominantly rounded, trace to occasionally common dolomitic and siliceous cement, trace calcareous cement in part, nil to trace brown grey argillaceous matrix, trace to common lithic grains, trace carbonaceous detritus and mica, rare glauconite and pyrite, fair to very good visual porosity.

SHOWS: The sandstone has trace to 10% dull white yellow to yellow green spotty fluorescence giving a very slow diffuse cut fluorescence and a very dull yellow green crush cut fluoresence with a faint thin ring residual. The core samples had a slight

to moderate hydrocarbon odor.

Note: Fluorescence only seen in the core samples. No fluorescence was seen in the cuttings samples.

2881 - 2950 metres
SANDSTONE: very light to light grey, clear to dark grey grains, friable to moderately hard, coarse to very coarse, conglomeratic in part, poorly to moderately sorted, subrounded to rounded, trace siliceous and dolomitic cement, trace arenaceous matrix, trace pyrite and lithic grains, fair to good porosity, no fluorescence.

2950 - 3040 metres (TD)

SANDSTONE: off white to medium brown grey, friable to moderately hard, fine to occasionally medium, moderately sorted, subangular to subrounded, common siliceous cement, trace dolomite cement, trace to occasionally common pyrite, trace glauconite and mica, very poor to poor visual porosity, no fluorescence, interbedded with

SILTSTONE, medium grey to medium brown grey, very argillaceous, arenaceous in part, dolomitic in part, trace to common carbonaceous flecks, trace nodular pyrite and glauconite, moderately hard, blocky.

5. TESTING AND EVALUATION

A. Wireline Logs

The following is a summary of the logs run on Terakihi No.1:

Depth	Hole Size	Logs Run
1141	17.5"	Run 1: BHC-GR-CAL
3040	12.25"	Run 1: DLL-MSFL-CNL-LDL-GR-SF-CAL Run 2: RFT Pretests/sample Run 3: RFT Sampling Run 4: BHC-GR-CAL Run 5: SHDT Run 6: WST Run 7: CST (Shot 30, recover 27)

B. Coring

Two full hole cores were cut using fiberglass sleeves. On both cores the sleeve broke and became jammed in the outer barrel. The cores were cut as follows (see Appendix D, Core descriptions for detailed descriptions):

. CORE No.1: 2844.0m - 2862.5m

CUT: 18.5m

RECOVERED: 12.6m (68%)

LITHOLOGY: 100% Sandstone with fair to good shows.

CORE No.2: 2862.5m - 2881.0m

CUT: 18.5m

RECOVERED: 9.9m (53.5%)

LITHOLOGY: 100% Sandstone with trace to poor shows.

C. Testing

No DST's or production tests were run. RFT's were run with the following recoverys.

RFT run 1 at 2841m: 3.1 m³ of gas and 17.7 liters of foamy mid

brown oil.

RFT run 2 at 2851m: 3.1 m³ of gas and 17.7 liters of foamy mid

brown oil. The second chamber was kept sealed for later analysis at reservoir

pressure.

Gas analysis for these samples were as follows: RFT 1

Sample 1 (2841m): Gas Analysis

	C1	; C2	C3	iC4	nC4	; C5 ;	C6 ¦
ppm	580640	90440	; 33820	6200	6540	; 1440 ;	trace;
rel %	80.7	12.6	; 4.7	0.9	0.9	; 0.2 ;	

Total Gas was 92.3%

CO2 was 0.2%

H2S was 10 ppm

SG of the gas = 0.69

RFT 2

Sample 1 (2851m): Gas Analysis

+	C2	C3 .	¦ iC4	nC4	; C5 ;	C6 ;
ppm	104720	37380 4.9	5952 0.8	¦ 6104 ¦ 0.8	; 1547 ; ; 0.2 ;	trace;

Total Gas was 92.8%

CO2 was 0.2%

H2S was 60 ppm

SG of the gas = 0.70

A comprehensive list of RFT pressures is given in Appendix 1. Table 6

6 DATA INVENTORY

The following were supplied to ESSO Australia ltd directly from the Southern Cross:

Weekly Geological and Engineering Report
Daily Hydraulics Printouts
Daily Engineering Reports
Formation Evaluation Log (supplied as required)

3 sets of washed and dried cuttings samples 1 set geochemical samples 1 set air dried bulk sample Miscellaneous RFT fluid samples

At the end of the well all the Tritium equipment, including all unused consumables supplied by Esso, was packed up and returned to Esso.

During and at the completion of the well, six copies of a Final Well Report was compiled by Exlog personal. Five of these were forwarded to ESSO offices in Sydney and Sale. A copy was retained by Exlog in Perth. Exlog also retains at its Perth office copies of all data disks.

EXPLORATION LOGGING will use all reasonable diligence to maintain and store the listed information and items in a manner to reasonably prevent damage or loss. Provided, however, EXPLORATION LOGGING assumes no responsibility for the loss, damage or theft of the items or the information contained herein and shall not be liable to the operator in any such event, irrespective of cause, fault or the active or passive negligence of EXPLORATION LOGGING or its employees.

7 CONCLUSIONS

Terakihi No.1 was a wildcat exploration well drilled in VIC/P24, Bass Strait, by the semi-submersable drilling rig Southern Cross. The well was spudded on the 30 March 1990 and reached a Total Depth of 3040m on the 14th April 1990. A total of 6 bits (8 bit runs) were used to drill 2616m in 113.7 hrs (on bottom) at an average rate of penetration of 23.1 m/hr. Two 18.5m cores were cut, with Core-1 recovering 12.6m of sandstone with good shows, and Core-2 recovering 9.9m of sandstone with only minor shows.

The primary objective of the well was to evaluate the hydrocarbon content of an erosional remnant mapped at the top of the Latrobe Group and sealed by the Lakes Entrance Formation. This was achieved with 15m of gross pay being mapped in the Top Latrobe Group sand.

The normal pore pressure gradient was estimated as 8.5 ppg (fresh to brackish water) and all monitored pressure parameters indicated that the well was normally pressured throughout and no evidence of any overpressuring was seen. RFT's run in the top Latrobe sands indicated a formation pore pressure gradient of 8.35 ppg EMW.

The fracture pressure was estimated using leak off test data and the constant effective stress ratio method. Fracture pressures were always greater than both the mud hydrostatic and effective circulating density and no downhole mud losses due to hydraulic fracturing were noted.

PE 602108

PE602108

This is an enclosure indicator page. The enclosure PE602108 is enclosed within the container PE903385 at this location in this document.

The enclosure PE602108 has the following characteristics: ITEM_BARCODE = PE602108 CONTAINER_BARCODE = PE903385 NAME = Drilling Data Pressure Log BASIN = GIPPSLAND PERMIT = VIC/P24 TYPE = WELL SUBTYPE = WELL_LOG DESCRIPTION = Drilling Data Pressure Log, 1:2500, (enclosure from Final Well Report--attachment to WCR) for Terakihi-1 REMARKS = DATE_CREATED = DATE_RECEIVED = 22/06/90 $W_NO = W1025$ WELL_NAME = Terakihi-1 CONTRACTOR = EXLOGCLIENT_OP_CO = Esso Australia Ltd

(Inserted by DNRE - Vic Govt Mines Dept)

ii. Temperature Data Pressure Plot 7 1:2500

PE602109

PE602109

This is an enclosure indicator page. The enclosure PE602109 is enclosed within the container PE903385 at this location in this document.

The enclosure PE602109 has the following characteristics:

ITEM_BARCODE = PE602109
CONTAINER_BARCODE = PE903385

NAME = Terakihi 1 Temperature Analysis Log

BASIN = GIPPSLAND PERMIT = VIC/P24

TYPE = WELL

SUBTYPE = WELL_LOG

DESCRIPTION = Terakihi 1 Temperature Analysis Log,

1:2500, (enclosure from Final Well

Report--attachment to WCR)

REMARKS =

DATE_CREATED =

DATE_RECEIVED = 22/06/90

 $W_NO = W1025$

ii. Weekly Geological-Engineering Reports

30th Mar - 4 APR 1990

GEOLOGICAL-ENGINEERING REPORT No.1

ESSO AUSTRALIA Ltd.

Spud - 1150 meters

erakihi No.1

EXLOG U244 M. Sale, D. Thornton

#### OPERATIONS SUMMARY

Terakihi No.1 was spudded on the 30th March 1990 at 06:30 hours by the semi-submersible drilling rig "Southern Cross". All depths unless otherwise stated are in metres along hole below the RKB. RKB to mean sealevel was 21m and RKB to seafloor was 424 metres (sea depth 401m).

26" Hole Section : Spud to 551 metres.

After ballasting the rig to drilling depth, the TGB was run to the seafloor, due to a considerable angle, it was pulled and a section of 13.375" casing welded to it to aid in stability. NB#1, a HTC R1 26" run with a 26" hole opener, was picked up and spudded Terakihi No.1 at 06:30 hrs on the 30th March 1990. This bit drilled to 551m, a distance of 127m in 3.3 hrs at an average rate of penetration of 38.5 m/hr. The drilling fluid was seawater with Hi Vis sweeps being circulated on each connection. At 551m the hole was swept with a 100 bbl Hi Visc pill, a survey dropped and the bit tripped to the seafloor. The bit was tripped back to bottom with no fill and a 250 bbl Hi Visc pill spotted, and the bit pulled to run casing.

10 joints of 20", X56, 94ppf casing were then run and the shoe set at 540m. The casing was cemented with 750 sx class "G" cement.

#### 17.5" Hole Section: 551 - 1141 meters

After running the marine riser and BOP stack the 17.5" BHA and NB#2, a HTC X3A was picked up and run in the hole to the top of cement at 533m. The cement and shoe were drilled to 551m and new hole drilled to 1141m with no problems. At 1141m bottoms up was circulated, and a survey dropped (dev = 0.25 deg at 1141m). A 100 bbl Hi Visc slug was pumped around the hole to sweep the riser, and a slug pumped prior to pulling out of the hole to the shoe, where the survey barrel was retrieved. The bit was then run back to bottom with no fill being recorded. Bottoms up was then circulated to condition the mud and a slug pumped prior to pulling out of the hole to run wireline logs. The 17.5" BHA was laid out and wireline logs were run (BHC-GR-Cal) with no problems. The bit made 590m in 11.1 hrs (on bottom rotating) with an average rate of penetration of 53.2 m/hr, and was graded T2 B2 G IN.

60 joints of K55, 54.5 lb/ft, 13.375" casing were then run with the shoe set at 1124m. The casing was cemented with 1000 sacks of class "G" cement.

#### 12.25" Hole Section: 1141 - 1150 meters

After testing the stack and picking up the 12.25" BHA, NB#3 a HYCALOG PDC DS40, was run in the hole and drilled cement and the shoe track from 1099m. New hole was drilled to 1144m where bottoms was circulated and a leak off test taken to a gauge pressure of 1300 psi to give a fracture pressure of 16.0 ppg EMW.

Current operation as at 00:00 hrs 4th April 1990 is drilling ahead with NB#2 from 1150m.

#### BOREHOLE CONDITION

No hole problems were seen whilst drilling either the 26" or 17.5" hole sections. No fill was noted on the wiper trip at 1141m. A slight overpull was recorded on all 15 stands pulled to the shoe at 1141m of a maximum of 50 Klb, suggesting an in gauge hole. Trip gas recorded during this wiper trip indicated however, the hole may be washed out in some places.

#### FORMATION PRESSURE

#### a) Pore Pressure.

As the 26" hole was drilled with returns to the seafloor and therefore no meaningful pressure analysis is possible for this section (424m - 551m).

Connection gas encountered from 551m - 700m whilst drilling with 8.7 ppg mud indicates an estimated pore pressure in the region of 8.6 - 8.7 ppg EQMD, which is within the region expected from a salt water pressure gradient. The origin of this gas is thought to be from a biogenic window within the Gippsland Limestone. By 700m mud weight increased to 9.3 ppg and no connection gas was encountered. Other indicators suggest that the pore pressure gradient remained normal in the 17.5" hole.

The 12.25" hole section to 1150m appears to be normally pressured. Dxc exhibited a normal trend with only minor variation due to slight lithological changes. Gas values were generally fairly low and no connection or high trip gasses were recorded. Cutting were generally blocky and cavings were small, blocky and of only minor quantity. Flowline temperature was damped and unresponsive due to heat loss in the riser and the frequent additions of new mud and water.

#### b) Fracture Pressure

A leak off test was run at 1144m and taken to a surface pressure of 1300 psi with a 9.2 ppg mud weight to give a formation fracture pressure of 16.0 ppg EMW.

OPERATIONS SUMMARY

12.25" Hole Section: 1141 - 2844 meters

After testing the stack and picking up the 12.25" BHA, NB#3 a Hycalog PDC DS40, was run in the hole and drilled cement and the shoe track from 1100m. New hole was drilled to 1144m where bottoms were circulated and a leak off test taken to a gauge pressure of 1300 psi to give a fracture pressure of 16.0 ppg EMW.

Drilling continued with NB#3 from 1144m to 1214m where returns were circulated, a survey dropped (dev = 0.5 deg at 1214m) and the bit pulled due to low rate of penetration. No overpull was recorded during the trip out. NB#3 drilled from 1141m to 1214m, a distance of 73m, in 5.7 hrs at an average rate of penetration of 12.4 m/hr and was graded 10% worn. The lithology was limestone grading to calcareous claystone.

NB#4, a HTC ATJ1 12.25" was picked up and run in the hole with no problems and no fill and drilled at rates of penetration varying from 10 to 30 m/hr. At 1774m a survey was run (Dev = 2.75 deg S52W) and the bit pulled due to high bit hours and low rate of penetration. This bit drilled 560m in 33.9 hrs at an average rate of penetration of 16.5 m/hr and was graded as T3 B3 G0. The lithology was limestone occasionally grading to calcareous claystone. Tight hole was recorded on the trip out with up to 80 klb overpull being recorded from most stands to the shoe.

RRB#3, a Hycalog PDC DS40 12.25" bit was then picked up and run in the hole with no problems and drilled through the Gippsland Limestone to 2273m at rates of penetration ranging from 10 to 40 m/hr. At 2273m a Hi Vis pill was circulated, a survey dropped (misrun) and a 20 stand wiper trip made with no hole problems. Drilling then continued through the Gippsland Limestone at rate of penetration varying from 10 to 25 m/hr to 2475m where the rate of penetration increased to over 30 m/hr marking the top of the Lakes Entrance formation. At 2506m the Seawater-gel mud system was displaced with a KCl-Polymer mud system. Drilling continued through the calcareous claystones of the Lakes Entrance Formation at rates of penetration varying from 20 to 50 m/hr. At 2841m the rate of penetration increased to over 60 m/hr and a flow check made at 2844m with no flow. This drilling break marked the top of the Latrobe Group, the primary target, and bottoms up were circulated with a maximum gas of 16% (800 u) and C1-C5 being recorded. Based on this it was decided to cut a core and a survey was dropped (Dev = 2.75 deg S13E at 2844m). A wiper trip was then made to the shoe with overpull of up to 100 klb being recorded from the interval 2776m - 2498m on the trip out. The bit was run back to bottom with no problems and bottoms up circulated with a trip gas of 64u (1.28%). The bit was then pulled with no hole problems. RRB#3 drilled from 1774m - 2844m, a distance of 1070m in 41.2 hrs (on bottom) at rates of

penetration varying from 10 to 60 m/hr and averaging 26 m/hr.

NB#5, a Christensen RC 476 12.25" core bit, was picked up and run in to cut core No.1. Tight hole was noted on the last stand of the trip in, the kelly picked up and the interval 2830m - 2844m reamed. Bottoms up were then circulated prior to cutting core No.1 with a trip gas of 13u (0.26%) being recorded.

#### BOREHOLE CONDITION

No hole problems were seen while drilling, however tight hole was noted on the bit trip at 1774m with up to 80 klb overpull being noted on the trip out. The trip in was clean and it would appear that the tight hole was due to slight hydration and swelling of the Gippsland Limestone. No hole problems were noted on the wiper trip at 2273m.

Up to 100 klb overpull was recorded from the interval 2776m - 2498m on the wiper trip at 2844m. The tight hole was attributed to hydrating and swelling of clays in the Lakes Entrance Formation and one trip through this section was all that was required to stabilize the hole. The interval 2830m - 2844m had to be reamed on the trip in with the core barrel.

#### FORMATION PRESSURE

#### a) Pore Pressure.

Pore pressure through the 12.25" hole section appears to have remained normal at 8.5 ppg EMW. The most reliable pressure indicators through this section were gas, which was generally low, and cavings which were generally only minor. Hole problems were generally minor and no fill was recorded after trips. While trip gasses of up to 64u were recorded the peaks were fairly sharp and gas values quickly returned to normal after bottoms up.

he Dxc plot was of little value below 1774m due to the use of a PDC bit below this depth as the Dxc equation is not applicable to this type of bit.

Flowline temperature was damped and unresponsive due to heat loss in the riser and was of little value in pressure detection.

#### b) Fracture Pressure

A leak off test was run at 1144m and taken to a surface pressure of 1300 psi with a 9.2 ppg mud weight to give a formation fracture pressure of 16.0 ppg EMW. Fracture pressures while drilling remained above this to reach a maximum of 20.6 ppg EMW at 2840m and it was considered unlikely that any mud losses due to hydraulic fracturing would occur.

Current operation at 24:00 hrs 11/04/90 is circulate bottoms up prior to cutting core 1.

11th APR - 18th APR 1990 2844 - 3040 meters

EXLOG U244 D. Marburger, D. New.

OPERATIONS SUMMARY

12.25" Hole Section: 2844 - 3040 meters

After finishing circulating bottoms up core 1 was cut from 2844m to 2862.5m (18.5m) in 1.4 hrs at an average rate of penetration of 13.2 m/hr. Tight hole was noted from the first two stands of the trip out with a maximum overpull of 100 klb. It was not possible to pump a slug resulting in a wet trip. While breaking out the core barrel it was discovered that the top joint of the inner fiberglass sleeve had become jammed in the outer barrel and had broken off at both the top and bottom. Both sleeves were layed down and 12.6m (68%) of sandstone recovered. As there were indications of hydrocarbons in the bottom of the core it was decided to cut another core.

The core barrel and RRCB#1 were run in the hole to 2805m and the interval 2805m - 2862.5m reamed with tight hole being noted at 2839m. Bottoms up were circulated with a trip gas of 110 units (2.2%) and the ball dropped. When the ball seated the pump pressure surged to 2000+ psi before returning to normal. It is likely that the fiberglass sleeve was jammed against the outer barrel and that this pressure surge burst the sleeve. Core 2 was then cut from 2862.5m to 2881m, a distance of 18.5m, in 1.7 hrs at an average rate of penetration of 10.9 m/hr. Tight hole was again noted on the trip out and it was necessary to pick up the kelly and backream from 2881m - 2788m. This tight hole may have been due to cuttings packing off round the BHA as the annular velocities while coring were low. The core sleeves were layed down (the top sleeve was broken about 5m from the top) and 9.9m (53.5%) of sandstone recovered.

The BOP's were tested and NB#5, a Smith F27D, picked up and run in the hole to 2800m where the kelly was picked up and the interval 2800m -2881m reamed/washed to bottom. Drilling continued through the sandstones of the Latrobe Group at rates of penetration varying from 60 to 2 m/hr. The torque seen on this bit run was erratic and often very high and the bit had to be pulled up and worked back to bottom on many occasions. At 3040m TD was reached, bottoms up circulated, and a 10 stand wiper trip made with only minor overpull being noted on the trip out. Bottoms up were again circulated, a survey dropped and the bit pulled to run logs. NB#5 drilled 159m in 15.4 hrs (on bottom) at an average rate of penetration of 10.3 m/hr.

Wireline logs were then run as follows:

Run 1: DLL-MSFL-LDT-CNL-GR-Cal

Run 2: RFT (10 pressure points, 1 sample)

Run 3: RFT (Two samples)

Run 4: BHC-GR-Cal

Run 5: SHDT

Run 6: WST

Run 7: CST (Shot 30, recovered 27)

On the basis of core and log data it was decided to case and suspend the well and RRB#6 was picked up and run in the hole for a wiper The interval 2995m to 3040m was reamed/washed on the trip in and a 100 bbl Hi Vis pill circulated with common small blocky to platy cavings (from the Latrobe Group?) being noted on bottoms up. The kelly was rat holed and an attempt made to pull out of the hole. This was not possible due to the BHA packing off and the kelly picked up and a 200 bbl Hi Vis pill circulated. Common fresh platy cavings (also from the Latrobe Group) were noted on bottoms up. hole instability did not appear to be due to overpressuring as the cavings were fairly small and were not curved. It is possible that the Latrobe Group siltstones are microfractured as this would produce the type of cavings seen. A wiper trip was then made to 2450m with the kelly being used to pump out singles over the interval 3010m - 2995m on the trip out and the same interval being reamed on the trip in. A 90 bbl 15.3 ppg pill was circulated and the bit pulled with the interval 3010m - 2995m being worked on the trip out.

222 joints of 9.625" N80 47 lb/ft casing were then run and cemented with the shoe at 3001m. The wellhead was then secured and the rig released.

#### BOREHOLE CONDITION

On both trips out of the hole with the core barrel the BHA was initially packed off and up to 100 klb overpull was recorded. This was probably due to the low flow rates and annular velocities used while coring being insufficient to remove the cuttings and lost core from the hole.

Hole problems were also noted on the wiper trip after logging with the interval 2995m to 3040m was reamed/washed on the trip in. A 100 bbl Hi Vis pill was circulated at 3040m with common small blocky to platy cayings (from the Latrobe Group?) being noted on bottoms up. The kelly was rat holed and an attempt made to pull out of the hole. This was not possible due to the BHA packing off and the kelly picked up and a 200 bbl Hi Vis pill circulated. Common fresh platy cavings (also from the Latrobe Group) were noted on bottoms up. hole instability did not appear to be due to overpressuring as the cavings were fairly small and were not curved. It is possible that the Latrobe Group siltstones are microfractured as this would produce the type of cavings seen. A wiper trip was then made to 2450m with the kelly being used to pump out singles over the interval 3010m -2995m on the trip out and the same interval being reamed on the trip in. A 90 bbl 15.3 ppg pill was circulated and the bit pulled with the interval 3010m - 2995m being worked on the trip out.

From 2881m to 3040m very high, erratic, torque was recorded. frequently causing the rotary table to stall out necessatating the bit being pulled up and worked back to bottom. This tight hole may have been due to the stabilizer hanging up in in gauge hole however the nature of the cutting seen while circulating Hi Vis pills after logging indicates that the siltstones of the Latrobe may be microfractured. If this were the case then the high torque may have been produced by the action of the bit on the fractures rather than the stabilizer.

#### FORMATION PRESSURE

#### a) Pore Pressure.

Pore pressure through the 12.25" hole section appears to have remained normal at 8.5 ppg EMW. The most reliable pressure indicators through this section were gas, which was generally low, and cavings which were generally only minor. Hole problems were generally minor and no fill was recorded after trips. While trip gasses of up to 110u (2.2%) were recorded the peaks were fairly sharp and gas values quickly returned to normal after bottoms up.

The tight hole seen on trips and while drilling below 2844m was attributed cuttings packing off round the BHA and to the stabilizer hanging up in gauge hole and was not an indicator of increasing pore pressure.

Below 2881m a conventional insert bit was used and Dxc indicated a normal trend.

Flowline temperature was damped and unresponsive due to heat loss in the riser and pits and was of little value in pressure detection. A gradual warming trend was noted to 2880m where both temperature in and temperature out showed a trend reversal and from 2880m to 3040m temperatures decreased. However delta T remained constant and this trend reversal was attributed to a decreasing ambient temperature at this time.

RFT's were run through the Latrobe sands and indicated that the formation was normally pressured at 8.35 ppg EMW and indicated a maximum formation pressure of 4048 psi at 2868.5m to give an extrapolated bottom hole pressure of 4292.4 psi. The RFT data indicates a near freshwater gradient for this well and hence a lower than estimated normal formation pressure gradient.

#### b) Fracture Pressure

A leak off test was run at 1144m and taken to a surface pressure of 1300 psi with a 9.2 ppg mud weight to give a formation fracture pressure of 16.0 ppg EMW. Fracture pressures while drilling remained above this to reach a maximum of 21.5 ppg EMW at 2840m (base of the Lakes Entrance Formation) and it was considered unlikely that any mud losses due to hydraulic fracturing would occur.

D. CORE DESCRIPTIONS

#### CORE DESCRIPTIONS

CORE No.1: 2844m - 2862.5m

CUT: 18.5m

REC: 12.6m (68%)

Note: The core was cut using a fiberglass sleeve and descriptions are based on chip samples only.

SANDSTONE: off white to light grey, clear to ligh grey grains, fine and very coarse (bimodal), very poorly sorted, rounded to subabgular, trace siliceous cement, very rare argillaceous and arenaceous matrix, trace lithics, very rare pyrite, good visual porosity. The sandstone has 60 - 70% moderately bright yellow - white solid to patchy fluorescence with a moderately fast streaming, moderately bright yellow/white cut fluorescence and a bright yellow/white crush cut fluorescence. Thin bright yellow ring residual. The sample had a strong hydrocarbon odour.

2845.0m SANDSTONE: off white, clear to off white, fine to very coarse, very poorly sorted, subangular to well rounded, no cement or matrix, trace carbonaceous flecks and lithic grains, very friable, excellent visual porosity. The sandstone has 50% moderately bright yellow/white patchey flourescence with a very fast to instant streaming cut and bright yellow thin ring residual. The sample had a hydrocarbon ordour.

SANDSTONE: off white to light grey, clear to medium grey (smokey) grains, medium to very coarse, poorly sorted, subangular to rounded, no cement or matrix, trace lithic grains, firm, very good to excellent visual porosity. The sandstone has 70% - 90% bright yellow/white solid to patchey flourescence with a moderately bright fast streaming yellow white cut flourescence and a bright yellow/white thin ring residual. The sample had a strong hydrocarbon ordour.

2847.2m SANDSTONE: as above with 70% - 80% bright yellow/white solid to patchey fluorescence and instant bright yellow / white cut fluorescence with a bright yellow/white thin ring residule.

2848.4m SANDSTONE: as above becoming medium to conglomeratic with trace glauconite and biotite. The fluorescence was 40% moderately bright yellow/white with an instant moderately bright yellow/white cut fluorescence and a moderately bright thin ring residual.

- SANDSTONE: as above, dominantly very coarse, excellent visual porosity. The sandstone has 30% to 40% dull to dominantly moderately bright patchy to spotty yellow green to yellow white fluorescence with an instant moderately bright yellow white cut and a moderately bright yellow white thin ring residule. This sample had a hydrocarbon ordour.
- SANDSTONE: white to very light grey, clear to light grey grains, medium to conglomerativ, dominantly very coarse, poorly sorted, subrounded to well rounded, no cement or matrix, trace to common lithics, trace biotite, loose to very friable, execellent visual porosity. The sandstone has 5% to 10% dull to moderately bright yellow white spotty fluorescence with an instant dull yellow white cut flourescence and dull yellow white thin ring residule. The sample had a slight hydrocarbon ordour.
- 2852.4m SANDSTONE: as above, dominantly very coarse to conglomeratic and moderately sorted. The sandstone had 5% to 10% fluorescence and cut as above.
- 2853.8m SANDSTONE: as above with trace to 5% fluorescence and cut as above.
- 2855.2m SANDSTONE: as above with trace lithics pyrite and mica. The sandstone has trace to 5% dull yellow white very spotty fluorescence with a dull yellow white, moderately fast, cut fluorescence and a dull yellow white very thin ring residule and trace to moderate hydrocarbon odour.
- SANDSTONE: off white medium grey, clear to medium grey grains, medium to conglomeratic, dominantly very coarse, moderately sorted, subrounded to rounded, rare dolomite cement, trace to common siliceous cement, very rare silty matrix, trace to moderate lithic grains, hard to very hard, moderate visual porosity. The sandstone has 30% to 40% patchy moderately bright yellow white fluorescence with a moderately bright fast streaming yellow white cut fluorescence and a moderate hydrocarbon odour.
- 2856.6m 2862.5m NO RECOVERY

CORE No.2: 2862.5m - 2881.0m

CUT: 18.5m

REC: 9.9m (53.5%)

off white to light grey, clear to medium grey SANDSTONE: 2862.5m grains, fine to conglomeratic, dominantly very coarse, very poorly sorted, subangular to well sounded, no cement or matrix, trace muscovite and lithic fragments, trace pyrite, friable, ececellent visual porosity. loose to has trace to 10% dull yellow white sandstone fluorescence with a dull yellow white very slow pluming cut fluorescence and a dull to moderately bright very thin ring residual. The sample has a slight hydrocarbon odour.

as above with trace to common lithics. The SANDSTONE: 2863.0m sandstone has a trace dull yellow green flourescence slow diffuse dull yellow green very fluorescence and a very dull crush cut fluorescence with a very dull thin ring residual.

SANDSTONE: as above with fluorescence and cut as above.

off white to medium grey, occasionaly brown SANDSTONE: grey, clear to dark grey grains, fine to conglomeratic. very poorly sorted, subangular to well rounded, trace calcareous and dolomitic cement, trace siliceous cement, rare quartz overgrowths, trace brown grey argillaceous matrix, common lithic grains, trace glauconite and pyrite. trace mica, friable to moderately hard, good to very good visual porosity. The sandstone has a trace dull yellow to milky spotty fluorescence with a very dull milky slow even fluorescence and a dull yellow white cruch cut fluorescence with a dull yellow white thin ring residual.

SANDSTONE: medium grey, clear to medium grey grains, fine to conglomeratic (bimodal), poorly sorted, subangular to subrounded, common to abundant dolomite cement, trace to common siliceous cement, trace calcareous cement, trace arenaceous and argillaceous matrix, trace carbonaceous flecks and mica, very hard, very poor visual porosity, trace dull orange mineral fluorescence with no cut or crush cut flourescence.

medium grey, clear to medium grey grains, SANDSTONE: grey, fine to medium light brown occasionaly conglomeratic (bimodal), moderately sorted, subangular to subrounded, trace dolomite and siliceous cement, grains, lithic common argillaceous matrix, carbonaceous flecks and mica, hard, poor to moderate visual The sandstone has a trace dull yellow green porosity. spotty fluorescence with no cut but a very weak dull yellow green crush cut and minor dull yellow green residual.

2865.5m

2866.8m

2868.3m

2869.7m

2871.1m

SANDSTONE, medium to light grey, clear to light grey grains, fine to medium and conglomeratic (bimodal), poorly to moderately sorted, subangular to subrounded, (rounded where conglomeratic), trace dolomite and siliceous cement, trace grey argillaceous matrix, trace to common lithic grains, trace muscovite and pyrite, hard, moderate to good visual porosity. The sandstone has a trace dull yellow green spotty fluorescence with a slow diffuse very faint yellow green cut fluorescence and a very dull yellow green crush cut fluorescence.

2872.4m

SANDSTONE: as above with trace glauconite and trace to 5% fluorescence and cut as above.

E. FORMATION EVALUATION LOG

#### PE602113

This is an enclosure indicator page. The enclosure PE602113 is enclosed within the container PE903385 at this location in this document.

The enclosure PE602113 has the following characteristics:

ITEM_BARCODE = PE602113
CONTAINER_BARCODE = PE903385

NAME = Formation Evaluation Log/Mud Log

BASIN = GIPPSLAND PERMIT = VIC/P24

TYPE = WELL

SUBTYPE = MUD_LOG

DESCRIPTION = Formation Evaluation Log/Mud Log

(enclosure from Final Well
Report--attachment to WCR) for
