PALYNOLOGICAL ANALYSIS,

PEP 100, OTWAY BASIN

by

M.K. MACPHAIL

Palaeontological report prepared 15 February 1991 for Gas & Fuel Exploration N/L

Constitute Palynologist, 20 Abbey St., Gladesville, NSW 2111

INTRODUCTION SUMMARY OF RESULTS GEOLOGICAL COMMENTS PALAEOENVIRONMENTS BIOSTRATIGRAPHY INTERPRETATIVE DATA BASIC DATA SPECIES CHECK LIST

#### INTRODUCTION

Nine sidewall cores, representing the interval 75.0m to 313.0m in Ingleby-1 were processed and examined for spore-pollen and dinoflagellates.

Yields and preservation are adequate to high, allowing most samples to be dated with confidence. The exception is the interval between 240.0-244.0m where either or both downhole caving and reworking has resulted in mixed Eocene and Mesozoic palynofloras.

Palynological determinations and interpreted lithological units are summarized below. Interpretative and basic data are given in Tables 1 and 2 respectively. Estimated TAI values of and dominant kerogen types present in each sample are given in Table 3. The stratigraphic distribution of all species is recorded in the attached range chart. Electric log data were unavailable.

#### SUMMARY

UNIT	ZONE	DEPTH RANGE (m)	ENVIRONMENT		
HEYTESBURY GP	P. tuberculatus	75.0 - 150.0	restricted marine

#### GEOLOGICAL COMMENTS

1. Middle? Albian, <u>C.</u> paradoxa Zone sediments which locally form the top of the Eumeralla Formation in Ingleby-1 are overlain sequentially by (a) Middle Eocene, marginal marine facies provisionally assigned to the Nirranda Group and (b) Late Oligocene-Early Miocene, restricted marine facies provisionally assigned to the Heytesbury Group. There is no definite evidence that the well intersected Late Cretaceous or Paleocene sediments. The sample spacing is too coarse to verify the existence or not of any unconformity between the Nirranda and Heytesbury Group facies.

1

- 2. As at Nalangil-1 (Macphail, 1991), the composition of the Tertiary palynofloras more closely resembles those found in the central west Murray Basin than in basins to the south-east. Based on time-range data from the Murray Basin, it is possible that the Middle <u>N. asperus</u> Zone sample at 202.0m may be as young as latest Eocene-Early Oligocene, Upper <u>N. asperus</u> Zone.
- 3. Because of difficulties in establishing whether Early Cretaceous palynomorphs are in situ or reworked in mixed palynofloras, it is uncertain whether the top of the Eumeralla Formation occurs at or below 244.0m.

The latter hypothesis is considered to be more likely for two reasons:

- (a) Both the Tertiary and Early Cletaceous palynomorphs at 244.0m [and at 240.0m] Ellip the Some degree of thermal maturity [3- to 3] onversely spore-pollen above 240.0m have TAI values within the immature range, making it unlikely that the Tertiary component at 244.0m is caved.
- (b) Sediments at 244.0m are overlain by essentially barren strata - a claystones at 240.0m interpreted as a decomposed tuff and, at 224.5-230.0m, decomposed basalts (hand-written SWC descriptions).
- 4. The observation (Table 3) that TAI values both uphole and downhole of the interval 240.0-244.0m is consistent with localized heating. On present indications, the basalt sampled at 230.0m will be Middle - Late Eocene and, less certain, extruded onto a landscape developed on Eumeralla Formation.

÷

3

- 5. The Middle Albian, <u>C. paradoxa</u> Zone date for the SWC at 248.0m is unusually young for the top of the Eumeralla Formation in the onshore Otway Basin. It is noted that <u>C. paradoxa</u> Zone sediments occur in Snail-1, offshore Torquay Sub-basin.
- 5. TAI values of 2+ to 3- indicate that sediments below 240.0m are within the mature phase of liquid hydrocarbon generation. Whilst these estimates need to be verified using vitrinite reflectance, it is certain that TAI values at TD do not reach the over-mature values [3+ to 4] found at similar depths [910 ft.] in e.g. Hindhaugh Creek-1. Kerogen extracts are dominated by biodegraded structured and unstructured terrestrial material except at 313.0m which yielded very well preserved plant material, primarily derived from woody plants.
- 6. The well terminated within the Eumeralla Formation (C. striatus Zone sediments).

#### PALAEOENVIRONMENTS

- 1. The relative abundance of marine dinoflagellates and spore-pollen indicate a progressive strengthening of the marine influence at Ingleby-1 from the Late Eocene to the Early Miocene. At this time restricted marine conditions prevailed at the wellsite.
- 2. There is no definite evidence of any marine influence during the deposition of the claystone unit at 244.0m.
- 3. Low numbers of the algal cyst <u>Spheripollenites</u> <u>psilatus</u> demonstrate that the depositional environment during the <u>C. paradoxa</u> Zone was lacustrine. The excellent state of preservation of plant macerals at 313.0m indicate that this claystone accumulated under anaerobic conditions, eg. within a deep freshwater lake basin.

4

#### BIOSTRATIGRAPHY

Zone and age-determinations have been made using criteria proposed by Stover & Partridge (1973), Helby et al. (1987), Macphail & Truswell (1989) and unpublished observations made on Gippsland, Bass and Otway Basin wells. Zone names have not been altered to take account of nomenclatural changes to nominate species such as Triporopollenites bellus [now Canthiumidites bellus: see Mildenhall & Pocknall, 1989].

It is noted that spore-pollen criteria used to define the Late Eocene-Early Miocene Middle N. asperus, P. tuberculatus and T. bellus Zones are not always reliable away from the Gippsland Basin. The need for caution is emphasized by the occurrence in Ingleby-1 of a number of spore-pollen species previously recorded outside of the Murray Basin only in Nalangil-1.

For example, <u>Anacolosidites</u> <u>sectus</u> and <u>Tricolpites</u> <u>thomasii</u> are diagnostic of Middle <u>N</u>. <u>asperus</u> Zone sediments in the Gippsland Basin but range upwards into Early Oligocene, Upper <u>N. asperus</u> Zone strata in central west Murray Basin boreholes (see Macphail & Truswell, <u>ibid</u>). It is possible that the extended time distributions apply to wells in the northwestern sector of PEP 100.

Dinoflagellates may provide an alternative method (see Partridge, 1976) but to date the relevant, independently dated formations in the Gippsland Basin have not closely sampled or all the species systematically recorded.

Again some distributions appear to be time-transgressive. For example, <u>Corrudinium incompositum</u>, which in the Gippsland Basin is an index species for the Middle <u>N. asperus</u> Zone, ranges into the Upper <u>N. asperus</u> Zone in the Murray Basin. An apparently <u>in situ</u> specimen occurs in <u>P. tuberculatus</u> Zone sediments at 150.0m.

Crybelosporites striatus Zone 313.0m

Early Albian

į

The lowest sample available for analysis [SWC 3 at 313.0m] yielded a rich palynoflora dominated by several long-ranging Mesozoic spores and gymnosperm species, in particular <u>Cyathidites</u> spp., <u>Cicatricosisporites australiensis</u>, Baculatisporites comaumensis and Stereisporites spp.

These are associated with low numbers of the lacustrine algal

cyst <u>Spheripollenites</u> <u>psilatus</u> and the sample is distinguished from those upsection by the near perfect state of preservation of the spore-pollen and woody plant remains.

<u>Crybelosporites striatus and Trilobosporites trioreticulosus</u> are frequent-common, demonstrating that the sample is no older han <u>C. striatus</u> Zone. The assemblage includes the rare species, <u>Crybelosporites punctatus</u>.

The sample at 291.0m yield a very sparse assemblage of longranging Mesozoic species and caved Eccene pollen.

## Coptospora paradoxa Zone 248.0m

Middle? Albian

The palynoflora at 248.0m resembles that at 313.0m with two important exceptions: the palynoflora includes (i) large numbers of the nominate and index species of the <u>C. paradoxa</u> Zone, <u>Coptospora paradoxa</u>, and (ii) a very early occurrence of <u>Clavifera triplex</u>. This specimen appears to be <u>in situ</u>.

Although <u>C. triplex</u> first appears within the <u>C. paradoxa</u> Zone in northern Australia, it is not known to range lower than the <u>A. distocarinatus</u> Zone in southern Australia. A Middle rather than Albian age is implied. The absence of angiosperm pollen indicates that the palynoflora is older than Upper Albian, <u>P. pannosus</u> Zone. The relative abundance of <u>Triporoletes simplex</u>, Foraminisporis spp. and <u>Crybelosporites</u> striatus support an Early Cretaceous age.

## Lower N. asperus Zone 244.0m

Middle Eocene

ł

ł

The sparse palynofloras at 244.0m consists of long-ranging, Cretaceous spores, chiefly <u>Cicatricosisporites</u> and <u>Cyathidites</u> spp. These occur mixed with Tertiary pollen types, chiefly <u>Nothofagidites</u> (frequent-common) and <u>Proteacidites</u> and include one specimen of the Middle <u>N.</u> <u>asperus</u> Zone indicator, <u>P. reticulatus</u>. Several Tertiary marine dinocysts are present.

Although P. reticulatus is good evidence for minor caving, it noted that most Tertiary palynomorphs have the same TAI values [3-to 3] as the Mesozoic gymnosperms.

The sample is provisionally assigned to the Lower <u>N. asperus</u> Zone, based on <u>Rhoipites</u> <u>alveolatus</u> (see also Geological Comments). The sample is no older than <u>C. striatus</u> Zone, based on Trilobosporites trioreticulosus. The SWC at 240.0m yielded very low amounts of semi-opaque and opaque organic matter. Two specimens of Nothofagidites in this extract have TAI values within the range 3 to 3-.

Middle Nothofagidites asperus Zone 164.0m Late Eocene

One sample is assigned to this zone, based on the association of Aglaoreidia qualumis, Anacolosidites sectus, Tricolpites thomasii, Proteacidites nasus, P. pachypolus (frequent) and P. reticulatus at 236.0m. Dinoflagellates present in the assemblage include Corrudinium incompositum, Cordosphaeridium inodes, and an undescribed? species resembling Glaphyracysta retiintexta. The zone index species Triorites magnificus is absent.

An Early Oligocene, Upper <u>N. asperus</u> Zone age is possible but unlikely since the assemblage lacks definite Oligocene-Miocene indicators such as <u>Acaciapollenites miocenicus</u> and <u>Corsinipollenites</u>.

The palynoflora is extremely diverse and includes a number of rare species or uncommon records for this zone, e.g. <u>Dicolpopollis</u> cf metroxylonoides, <u>Gyropollis</u> psilatus, <u>Margocolporites vanwijhi</u>, <u>Ricciaesporites kawaraensis</u> and <u>Tricolpites trioblatus</u>. Also present and apparently in situ is a <u>Phimopollenites</u> sp. resembling the Late Cretaceous sp. <u>P. pannosus</u>. Reworked Early Cretaceous spp. are rare.

Proteacidites tuberculatus Zone 75.0-100.0m Oligocene late Early Miocene

The three palynofloras assigned to this zone are dominated by <u>Nothofagidites emarcidus-heterus</u>, <u>Araucariacites australis</u> and <u>Haloragacidites harrisii</u>. Marine dinoflagellates are frequent-abundant with the relative abundance reaching a maximum at 100.0m. All samples yielded low numbers of Early Cretaceous spores.

The lower boundary is picked at the first appearance of the zone index species <u>Cyatheacidites annulatus</u> at 150.0m. This is associated with <u>Foveotriletes</u> crater and the very rare species <u>Diporites aspis</u>. The assemblage includes an unexplained specimen of the Middle [-Upper] <u>N. asperus</u> Zone dinoflagellate <u>Corrudinium incompositum</u>. This is the youngest record to date of this species (cf Macphail & Truswell, 1989)

T

ļ

-----

TEL NULLUL VIEL

AND EVEL NE

The palynoflora at 100.0m includes Cyathidites subtilis and Foveotriletes lacunosus.

The upper boundary is placed at 75.0m, a palynoflora that includes significant numbers of <u>Cyatheacidites annulatus</u> in addition to the rare species <u>Perisyncolporites pokornyi</u> (see also Nalangil-1: Macphail, 1991) and <u>Reevesiapollenites</u> reticulatus. <u>Granodiporites nebulosus indicates that the</u> sample is unlikely to be younger than <u>P. tuberculatus</u> Zone. Indicator species of the <u>T. bellus</u> Zone are absent.

| 03  | 313.0     | 2+ to 3-  | well-preserved struct. (woody) |

- \* TAI estimates based on the chart of "Spore-pollen exine coloration with geothermal maturation" published as Colour Plate 1 in Traverse A. (1988) "Palaeo-palynology", Unwin Hyman, Boston. In this (standard) scale, TAI values of 1 to 2 are immature, TAI values of 2+ to 3 represent the mature phase of liquid hydrocarbon generation and TAI values of 3+ to 5 represent dry gas or barren.
- # Kerogen types are based on the classification of organic matter in clastic systems published by Hart, G.F. (1986) <u>Palynology</u> 10: 1-23. The majority of samples yielded low to significant amounts of fines of indeterminate origin.
