WESTERN DISTRICT SHALLOW BORES

A Summary of a Microfloral Examination of Western District Shallow Bores

A microscopic examination of Western District shallow bore holes was undertaken as a supplement to work in progress on the deep bores. (See Mines Department Report 1960/20 "A Microfloral and Microplankton Correlation of Western District Deep Bores at the Stage of Sampling Reached on 24/2/60".

Material from the Dergholm No.1 and Kanawinka No.1 bores was prepared over two years ago (Mines Dept. Unpublished Report 1957/40) but no systematic examination of samples was made.

It is felt that a clearer picture of Mesozoic sedimentation will be obtained by an examination of material from all bores available.

Preparations from the Dergholm area bores were obtained from earth-socket samplings which are more liable to contamination than corings. Some contamination of the Mesozoic section by Tertiary microfloras was observed.

No attempt has been made to compile a complete list of microfloral remains, a summary of pertinent species only being attempted.

An assessment has also been made of the Birregurra bore based on the microfloral work of Dr. I. Cookson.

Dergholm No.1 Bore

Locality:	P.Dergholm
Depth:	613 feet. Surface Level - 508'
Bore No.:	1

Nearly all preparations here contain Conifer pollens referable to the family Podocarpaceae, which are extremely numerous in some examples.

However in the 250 ft. region sporomorphs include *Neoraistrickia* sp., *Lycopodium sporites* sp., and *Cicatricosporites* sp., and it is apparent that the Mesozoic-Tertiary boundary is just above.

Further samplings above the boundary are necessary for confirmatory purposes, but lithological evidence agrees very well with this determination.

This microflora from below 250' resembles that from other Victorian pre-Upper Cretaceous predominantly non marine sediments.

A list of species from the 532 ft. level has been published by Cookson and Dettman 1958, P.120.

It is to be noted that no marine Upper Cretaceous sediments characterized by microplankton are present.

A summary of the microfloral content is tabulated below :-

<u>Depth</u>	<u>Depth Difference</u>	<u>Slide Nos.</u>	<u>Microflora</u>	<u>Age.</u>
249-52'	10'	138-9	Podocarpaceae pollens. Triorites sp. Cyathidites sp.	Tertiary.
252-68'	5'	140-1	Many Podocarp- aceae pollens.	-do-
268-73'	5'	142-3	Lycopodium austroclavatidites. Neoraistrickia cf. trunkatus. Triorites sp.	P r e D o m i n a n t l y N o n M a r i n e
273-8'	17'	116-17	Cicatricosporites australiensis. Podocarpaceae. L.austroclavatidites. Cyathidites sp. Osmundites comauensis etc.	m i n a n t l y N o n M a r i n e
295-300'	18'	171-3	C. australiensis, Podocarpaceae etc.	N
318-23'	109'	112-13	Taeniopteris spatulata O & M., macroscopic remains; Podocarpaceae etc.	n M a r i n e
532'		114-24	C. australiensis. Podocarpaceae, and see text.	Pre- Upper Cret- aceous

Kanawinka No.1 Bore

Locality: P.Kanawinka

Depth: 331 feet. Surface Level - 435'

Bore No: 1

The sequence of sedimentation here similar to the previous bore. Marine microplankton have been isolated from the Tertiary sequence, the Mesozoic-Tertiary boundary occurring between 221' and 265'.

More precise determination is impossible without further sampling as the 236' - 46' samples were barren.

In the Mesozoic section characteristic Pre-Upper Cretaceous predominantly non marine beds carried multitudinous Conifer pollens. The table below also lists a summary of sporomorphs and Cookson & Dettman 1958, p.120 list species from 329' (In this latter paper her Dergholm No.1 & 2 bores correspond to Mines Department Dergholm No.1 Bore and Kanawinka No.1 respectively).

<u>Well No.</u>	<u>Date</u>	<u>Depth</u>	<u>Depth Difference</u>	<u>Slide Nos.</u>	<u>Microfossils</u>
		206-9'	5'	300-1	Barren
'01		214-24'	-	174	Proteacidites sp. Multicellular algae.
'2		217-21'	15'	177-9	Nothofagus sp. Triorites Harrisii, Podocarpaceae Multicellular algae Hystrichosphaera ramosa.
'5		236-46'	19'	175	Barren
'11		265-7'	19'	164-6	Podocarpaceae, Triorites Harrisii, (Trisaccites micropterus).
		286-96'	20'	176	Cicatricosporites australiensis, but generally depauperate.
'01		322-4'	25'	170	Cicatricosporites australiensis.
'02		329-31'	41'	167-9	Trisaccites micropterus, Podocarpaceae, Cyathidites sp. Lycopodium sporites austroclad- vativides, Apiculatisporis sp. Cirratiradites spinulosus.
		372-8'		302-3	Barren.

Birregurra Bore

A geological column showing Mesozoic-Tertiary sedimentation in the Birregurra bore has been drawn, based on data by Drs.A.N.Carter and Isobel Cookson.

It can again be noted that no Upper Cretaceous marine sediments are intersected.

Conclusions

Close correlation between the rich floras of Dergholm 1 at 275' and 330' & Kanawinka seems possible, but no extensive corroborative quantitative and qualitative tests have been made.

Microfloral correlation of these bores in conjunction with deep bore microfossil correlation is an aid in delimiting the areal extent of Mesozoic sediments, particularly the Upper Cretaceous marine beds.
